

What is a Veneer?

These lower front teeth are starting to deteriorate. The biting surfaces are wearing down with areas that are chipping, and they have discolored over time. Veneers are an ideal treatment choice to restore their natural appearance.

Veneers can be used to change the color and shape of teeth in moderation. Only a small amount of the outer surface of the tooth must be removed in order for a veneer to be placed.

Veneers are thin shells of porcelain and are fabricated in a dental laboratory. The porcelain blends with the enamel of natural teeth and allows light to pass through, giving the veneers a natural appearance.

Veneers are a conservative restoration, used to restore natural teeth. The veneers are bonded onto the teeth and provide an esthetic result.
